## §1 January 20th, 2021

### §1.1 Intro to Riemann Mapping Theorem

Our first goal is to prove a fundamental theorem of Riemann on conformal mappings. We start with several preparations, including some detours. The theorem essentially says that lots of open sets in  $\mathbb{C}$  are holomorphically isomorphic, given that they satisfy some simple topological conditions.

### §1.2 Cauchy's Integral Formula

Recall Cauchy's formula:

$$f(z_0) = \frac{1}{2\pi i} \int_{\Gamma} \frac{f(z)}{z - z_0} dz$$

where  $\Gamma$  is a simple closed curve, piecewise differentiable,  $z_0 \in \text{Int}(\Gamma)$ , and  $f : \Omega \rightarrow \mathbb{C}$  is a holomorphic function, with  $\Omega$  open,  $\Omega \supset \Gamma \cup \text{Int}(\Gamma)$ .

If  $\Gamma$  is the circle  $|z - z_0| = R$ , we parameterize with  $z = Re^{i\theta} + z_0$  with  $\theta \in [0, 2\pi)$ . This gives

$$f(z_0) = \frac{1}{2\pi} \int_0^{2\pi} f(z_0 + Re^{i\theta}) d\theta,$$

which represents the average of  $f$  on the circle.

It follows that

$$|f(z_0)| \leq \max_{\partial B_R(z_0)} |f(z)|,$$

with equality if and only if  $f$  is constant.

If  $f : \Omega \rightarrow \mathbb{C}$  is holomorphic for  $\Omega$  connected, open and  $z_0 \in \Omega$ , then

$$|f(z_0)| \leq \sup_{z \in \Omega} |f(z)|$$

with equality if and only if  $f$  is constant.

### §1.3 Schwarz Lemma

#### Theorem 1 (Schwarz Lemma)

For  $f : B_1(0) \rightarrow \mathbb{C}$  holomorphic with  $|f(z)| \leq 1$  for all  $z$  and  $f(0) = 0$ . Then

$$|f(z)| \leq |z|, |f'(0)| \leq 1.$$

If for some  $z_0 \neq 0$ ,  $|f(z_0)| = |z_0|$  or if  $|f'(0)| = 1$  then  $f(z) = cz$  for some  $|c| = 1$ .

*Proof.* Define a function

$$g(z) = \begin{cases} f(z)/z, & \text{if } 0 < |z| \leq 1 \\ f'(0), & \text{if } z = 0 \end{cases}.$$

Note that  $g(z)$  is continuous since at zero,

$$\lim_{z \rightarrow 0} \frac{f(z)}{z} = \lim_{z \rightarrow 0} \frac{f(z) - f(0)}{z - 0} = f'(0).$$

Hence,  $|g(z)| \leq C < \infty$  using the Weierstrass Extreme Value theorem. If  $0 < \epsilon < |w| < r < 1$ , note that taking a Keyhole Contour, we have

$$g(w) = \frac{1}{2\pi i} \left( \int_{|z|=r} - \int_{|z|=\epsilon} \right) \frac{g(z)}{z-w} dz.$$

Note that

$$\left| \int_{|z|=\epsilon} \frac{g(z)}{z-w} dz \right| \leq (2\pi\epsilon) \cdot C \frac{1}{|w|-\epsilon} \xrightarrow{\epsilon \rightarrow 0} 0.$$

It follows that

$$g(w) = \frac{1}{2\pi i} \int_{|z|=r} \frac{g(z)}{z-w} dz$$

for  $0 < |w| < r$ . The right side is holomorphic in  $w$  if  $|w| < r$ , so it follows that

$$g(w) = \frac{1}{2\pi i} \int_{|z|=r} \frac{g(z)}{z-w} dz$$

is holomorphic in  $|z| < 1$ .

This can also be proved by taking a Taylor series about the origin. Since there is no constant term, we can divide by  $z$  to still have a convergent Taylor series.

If  $r < 1$ ,

$$\sup_{|z| \leq r} |g(z)| = \sup_{|z|=r} |g(z)| \leq \sup_{|z|=r} \frac{|f(z)|}{|z|} \leq \frac{1}{r}.$$

If we let  $r \uparrow 1$ , then we get  $\sup_{|z| < 1} |g(z)| \leq 1$ . It follows that  $|f(z)| \leq |z|$ ,  $|f'(0)| \leq 1$ .

If  $|f(z_0)| = |z_0|$  for some  $0 < |z_0| < 1$  then  $|g(z_0)| = 1$  and  $g$  is constant by the maximum principle so  $g(z) = c$ ,  $f(z) = cz$ . If  $|f'(0)| = 1$ , then  $|g(0)| = 1$  so  $g$  is constant and  $f = cz$ .  $\square$

## §1.4 Maximum Principles

In the above proof, we used the maximum principle. Some other versions we will use are the following:

If  $K \subset \mathbb{C}$  compact and  $f : K \rightarrow \mathbb{C}$  continuous, and the restriction of  $f$  to the interior of  $K$  is holomorphic, then

$$\sup_{z \in K} |f(z)| = \sup_{z \in \partial K} |f(z)|.$$

If  $\Omega$  is open and connected,  $f : \Omega \rightarrow \mathbb{C}$ ,  $z_0 \in \Omega$ , and  $|f(z_0)| = \sup_{z \in \Omega} |f(z)|$ , then  $f$  is constant. Applying this to  $e^f$  and using that  $|e^f| = e^{\operatorname{Re} f}$ , we find that

$$\operatorname{Re} f(z_0) = \sup_{z \in \Omega} \operatorname{Re} f(z),$$

implies that  $f$  is constant. We have the same result for  $\operatorname{Im} f$  by replacing  $f$  with  $-if$ .

## §2 January 25th, 2021

### §2.1 Uniform Convergence

**Remark 2.1.** They sometimes call open connected sets "regions".

**Definition 2.2** (Uniform Convergence). Let  $\Omega \subset \mathbb{C}$  be open. Let  $f_n : \Omega \rightarrow \mathbb{C}$  be holomorphic and  $f : \Omega \rightarrow \mathbb{C}$  a function so that  $\lim_{n \rightarrow \infty} \sup_{z \in K} |f(z) - f_n(z)| = 0$  for all  $K \subset \Omega$  compact (also denoted  $K \subset\subset \Omega$ ).

**Remark 2.3.** Recall from real analysis that  $f$  is a continuous function.

Some further remarks:

- It suffices to check the result for a sequence of compact subsets  $K_m$  so that  $\bigcup_m K_m^\circ = \Omega$ , then it suffices to check those. If  $K \subset\subset \Omega$ , then  $K$  is compact and covered by the union of the subsets so there exists a finite subcovering, and uniform convergence on the subcovering implies uniform convergence on  $K$ .
- It is often convenient to introduce  $\|g\|_K = \sup_{z \in K} |g(z)|$ . Uniform convergence can be restated as  $\|f_n - f\|_K \rightarrow 0$  for all  $K \subset\subset \Omega$ .
- If  $\|f_n - f\|_K \rightarrow 0$  for all  $K \subset\subset \Omega$ , then  $f$  is also holomorphic. It follows by passing to the limit in the Cauchy Integral formula. Namely, take  $\{z : |z - z_0| \leq R\} \subset \Omega$  and consider the points in  $|z_0 - \zeta| < R$ .

$$\begin{aligned} \left| f_n(\zeta) - \frac{1}{2\pi i} \int_{|z-z_0|=R} \frac{f(z)}{z-\zeta} dz \right| &= \left| \frac{1}{2\pi i} \int_{|z-z_0|=R} \frac{f_n(z)}{z-\zeta} dz - \frac{1}{2\pi i} \int_{|z-z_0|=R} \frac{f(z)}{z-\zeta} dz \right| \\ &\leq \frac{1}{2\pi} \frac{1}{R - |z_0 - \zeta|} \cdot (2\pi R) \|f_n - f\|_{|z-z_0|=R} \rightarrow 0. \end{aligned}$$

So it follows that

$$f(\zeta) = \lim_{n \rightarrow \infty} f_n(\zeta) = \frac{1}{2\pi i} \int_{|z-z_0|} \frac{f(z)}{z-\zeta} dz.$$

It follows that  $f$  continuous on  $|z - z_0| = R$  is holomorphic in  $\zeta \in \{|z - z_0| < R\}$ , so it follows that  $f$  is holomorphic.

- We can similarly show that

$$f_n^{(j)}(\zeta) = \frac{n!}{2\pi i} \int_{|z-z_0|=R} \frac{f_n(z)}{(z-\zeta)^{n+1}} dz$$

$$\text{and } \|f_n^{(j)} - f^{(j)}\|_K \rightarrow 0.$$

From the last item, we have the following theorem.

#### Theorem 2

If  $f_n \rightarrow f$  on compact subsets of  $\Omega$ , then if  $f_n$  is holomorphic we find that  $f$  is holomorphic and  $f_n^{(j)} \rightarrow f^{(j)}$  uniformly on compact subsets of  $\Omega$ .

**Theorem 3** (Hurwitz)

Let  $\Omega$  be a region,  $f : \Omega \rightarrow \mathbb{C}$  and  $f_n : \Omega \rightarrow \mathbb{C}$  holomorphic with  $f_n(\Omega) \subset \mathbb{C} \setminus \{0\}$ ,  $n \in \mathbb{N}$  and  $\|f_n - f\|_K \rightarrow 0$  for all compact subsets. Then either  $f \equiv 0$  or  $f(\Omega) \subset \mathbb{C} \setminus \{0\}$ .

*Proof.* If  $f$  is not identically zero on  $\omega$ , then since  $f$  is holomorphic, its zeros are isolated. If  $z_0 \in \Omega$ ,  $f(z_0) = 0$ , then there is  $\epsilon > 0$  so that when  $0 < |z - z_0| < \epsilon$ ,  $f(z) \neq 0$ .

Since  $f(z) \neq 0$  for  $|z - z_0| = \epsilon/2$ , by the Weierstrass theorem applied to  $|f|$  on  $|z - z_0| = \epsilon$ , we have  $|f(z)| \geq m > 0$  on  $\{|z - z_0| = \epsilon/2\} = \Gamma$ . If  $\|f_n - f\|_\Gamma \leq m/2$  for  $n \geq N$ , then

$$|f_n(z)| \geq |f(z)| - m/2 \geq m - m/2 = m/2$$

for  $z \in \Gamma$ . Hence, it follows that  $\|1/f_n - 1/f\|_\Gamma \rightarrow 0$  (we leave this as an exercise).

Since  $\|f'_n - f'\|_\Gamma \rightarrow 0$ , we find that  $\|f'_n/f_n - f'/f\| \rightarrow 0$  (another exercise) and hence

$$\frac{1}{2\pi i} \int_\Gamma \frac{f'_n}{f_n} dz \rightarrow \frac{1}{2\pi i} \int_\Gamma \frac{f'}{f} dz.$$

The integrand of the left hand side is  $(\log f_n)'$ , whose integral is 0, and the right side is the order of the zero of  $f$  at  $z_0$  by the argument principle. It follows that the order of  $z_0$  as a possible zero is 0, so  $f(z_0) \neq 0$ .  $\square$

**Theorem 4**

For  $\Omega \subset \mathbb{C}$  open,  $\mathcal{F}$  a set of holomorphic functions, the following are equivalent:

- for every  $K \subset\subset \Omega$   $\sup_{f \in \mathcal{F}} \|f\|_K < \infty$
- for every sequence  $(f_n)_{n \in \mathbb{N}} \subset \mathcal{F}$ , there is a subsequence  $(f_{n_j})_{j \in \mathbb{N}}$  with  $n_1 < n_2 < \dots$  so that  $(f_{n_j})_{j \in \mathbb{N}}$  is uniformly convergent on compact subsets of  $\Omega$ .

*Proof.* We first show 2 implies 1. If  $\sup_{f \in \mathcal{F}} \|f\|_K = \infty$ , then we can find for each  $n \in \mathbb{N}$   $f_n \in \mathcal{F}$  so that  $\|f_n\|_K \geq n$ . If we abstract a convergence subsequence, then  $\|f_{n_j} - f\|_K \leq C < \infty$  and  $\|f_{n_j}\|_K \leq \|f\|_K + C$ , while  $\|f_{n_j}\|_K \rightarrow \infty$ , a contradiction.  $\square$

## §3 January 27th, 2021

### §3.1 Uniform Convergence, continued

#### Theorem 5

For  $\Omega \subset \mathbb{C}$  open,  $\mathcal{F}$  a set of holomorphic functions, the following are equivalent:

- for every  $K \subset\subset \Omega$   $\sup_{f \in \mathcal{F}} \|f\|_K < \infty$
- for every sequence  $(f_n)_{n \in \mathbb{N}} \subset \mathcal{F}$ , there is a subsequence  $(f_{n_j})_{j \in \mathbb{N}}$  with  $n_1 < n_2 < \dots$  so that  $(f_{n_j})_{j \in \mathbb{N}}$  is uniformly convergent on compact subsets of  $\Omega$ .

I missed the beginning of the class, but I will add the proof of the theorem once notes are posted.

### §3.2 Metric Convergence

One can put a metric on holomorphic functions so that convergence in the metric is uniform convergence on compact sets. For  $f : \Omega \rightarrow \mathbb{C}$ , but  $K_n \Subset \Omega$  so that  $\bigcup_n K_n^\circ = \Omega$  and take

$$d(f, g) = \sum_{n=1}^{\infty} \frac{\|f - g\|_{K_n}}{1 + \|f - g\|_{K_n}} 2^{-n}.$$

### §3.3 Riemann Sphere

On the set  $\mathbb{C} \cup \{\infty\}$ , we consider the topology which makes it the Alexandroff(one-point) compactification of  $\mathbb{C}$ . If  $z \in \mathbb{C}$ , a neighborhood is one that contains a neighborhood in  $\mathbb{C}$  and a neighborhood of  $\infty$  is of the form  $\{\infty\} \cup (\mathbb{C} \setminus K)$  for  $K \Subset \mathbb{C}$ .

Let  $U_+ = \mathbb{C} \subset \mathbb{C} \cup \{\infty\}$  and  $U_- = (\mathbb{C} \setminus \{0\}) \cup \{\infty\}$ . Note that the union of the two sets covers the Riemann Sphere. Define  $\psi_+ : U_+ \rightarrow \mathbb{C}$  by  $\psi_+(z) = z$  and  $\psi_- : U_- \rightarrow \mathbb{C}$  is given by  $\psi_-(w) = 1/w$  if  $w \in \mathbb{C} \setminus \{\infty\}$  and 0 if  $w = \infty$ . Notice that these two functions are bijections.

If  $V \subset \mathbb{C} \cup \{\infty\}$  is open, a function  $f : V \rightarrow \mathbb{C}$  is holomorphic if

$$f|_{V \cup U_{\pm}} \circ (\psi_{\pm}|_{V \cup U_{\pm}})^{-1} : \psi_{\pm}(V \cup U_{\pm}) \rightarrow \mathbb{C}$$

is holomorphic. In this way, we know what holomorphic functions are on open sets of  $\mathbb{C} \cup \{\infty\}$ .

More generally, we can describe a Riemann surface in the following way - Let  $X$  be a topological space. Take  $\{(U_{\alpha}, z_{\alpha})\}_{\alpha \in I}$  where  $U_{\alpha} \subset X$  is open, and  $\bigcup_{\alpha \in I} U_{\alpha} = X$  and  $z_{\alpha} : U_{\alpha} \rightarrow \mathbb{C}$  is continuous,  $z_{\alpha}(U_{\alpha})$  is open and  $z_{\alpha}$  is a homeomorphism. The key requirement is that the maps  $z_{\alpha} \circ z_{\beta}^{-1} : z_{\beta}(U_{\alpha} \cap U_{\beta}) \rightarrow z_{\alpha}(U_{\alpha} \cap U_{\beta})$  are holomorphic.

Then, if  $U \subset X$  is open,  $f : U \rightarrow \mathbb{C}$  is holomorphic if for all  $\alpha \in I$ ,

$$f|_{U \cap U_{\alpha}} \circ (z_{\alpha}|_{U \cap U_{\alpha}})^{-1}$$

is holomorphic. Two such atlases give the same Riemann surface if put together, we get an atlas.

## §4 February 1st, 2021

### §4.1 Connectivity

**Definition 4.1.**  $\Omega \subset \mathbb{C}$  open is connected if  $\Omega = \Omega_1 \cup \Omega_2$  open with  $\Omega_1 \cap \Omega_2 = \emptyset$  implies that one of the two is empty. For open sets, this is equivalent to arcwise connected.

**Definition 4.2.** A set is arcwise connected if for every  $z_1, z_2 \in \Omega$ , there is a path  $\varphi : [0, 1] \rightarrow \Omega$  which is continuous and  $\varphi(0) = z_1, \varphi(1) = z_2$ .

**Definition 4.3.**  $\Omega$  is simply connected if for  $z_0 \in \Omega$ ,  $\Gamma : [0, 1] \rightarrow \Omega$  continuous and  $\Gamma(0) = \Gamma(1) = z_0$ , then there is  $G : [0, 1] \times [0, 1] \rightarrow \Omega$  continuous with  $G(t, 0) = \Gamma(t)$  for  $t \in [0, 1]$  and  $G(t, 1) = z_0$ , for  $t \in [0, 1]$ .

Simply connected corresponds to the idea of being able to continuously deform the set to a point for each point.

In  $\mathbb{R}^2 \cong \mathbb{C}$ ,  $\Omega$ -open simply connected is equivalent to  $(\mathbb{C} \cup \{\infty\}) \setminus \Omega$  is connected in  $\mathbb{C} \cup \{\infty\}$ . That is, if  $F = \mathbb{C} \cup \{\infty\} \setminus \Omega$ , which is closed in  $\mathbb{C} \cup \{\infty\}$ , with  $F \cap V_1 \cap V_2 = \emptyset$ , then at least one of the  $F \cap V_k = \emptyset$ . If  $0 \in \Omega$ , then  $\Omega$  is simply connected if and only if  $\{0\} \cup \{1/z : z \in \mathbb{C} \setminus \Omega\}$  is connected (this is a local representation).

- Take  $\Omega = \mathbb{C} \setminus \bigcup_{j=1}^m \{tz_j : t \in [1, \infty)\}$  for  $z_1, \dots, z_n \in \mathbb{C} \setminus \{0\}$ .
- $\mathbb{C} \setminus$  spirals.

#### Theorem 6 (Riemann Mapping Theorem)

If  $\Omega \subset \mathbb{C}$  open, connected, simply connected,  $\emptyset \neq \Omega \neq \mathbb{C}$ , then  $\Omega$  and  $\mathbb{D} = \{|z| < 1\}$  are holomorphic isomorphisms.

### §4.2 Fractional Linear Transformations

Recall that if  $f \in \text{Aut}(\mathbb{D})$  then  $f(z) = \frac{az+b}{cz+d}$ , which was proved using the Schwarz lemma. We view the fractional linear maps from a different context.

We define a map  $p : \mathbb{C}^2 \setminus \left\{ \begin{pmatrix} 0 \\ 0 \end{pmatrix} \right\} \rightarrow \mathbb{C} \cup \{\infty\}$  given by

$$p \left( \begin{pmatrix} z_1 \\ z_2 \end{pmatrix} \right) = \begin{cases} z_1/z_2 & \text{if } z_2 \neq 0 \\ \infty & \text{if } z_2 = 0 \end{cases}.$$

Then  $p(\xi) = p(\eta)$  if and only if  $\xi = \lambda\eta$  for  $\lambda \in \mathbb{C}^\times = \mathbb{C} \setminus \{0\}$ .

There is a larger group acting on  $\mathbb{C}^2 \setminus \left\{ \begin{pmatrix} 0 \\ 0 \end{pmatrix} \right\}$  given by  $GL(2, \mathbb{C})$  the invertible  $2 \times 2$  matrices in the natural way so that

$$A \begin{pmatrix} z_1 \\ z_2 \end{pmatrix} \mapsto \frac{A_{11}p(\xi) + A_{12}}{A_{21}p(\xi) + A_{22}}.$$

Define  $T_g : \mathbb{C} \cup \{\infty\} \rightarrow \mathbb{C} \cup \{\infty\}$  given by

$$T_g z = \frac{az + b}{cz + d},$$

with  $T_g(\infty) = \frac{a}{c}$ . We have the action  $T_g p(\xi) = p(g\xi)$  for  $g \in GL(2, \mathbb{C})$ .

This gives

$$\begin{aligned} T_{g_1} \circ T_{g_2} &= T_{g_1 g_2}, \\ (T_g)^{-1} &= T_{g^{-1}}. \end{aligned}$$

We can also ask about the fixed point:

$$T_g p(\xi) = p(\xi) \leftrightarrow p(\xi) = p(g\xi) \Leftrightarrow g\xi = \lambda\xi, \lambda \in C^\times$$

It follows that the fixed points of  $T_g$  correspond to the eigenvectors of  $GL(2, \mathbb{C})$ .

### §4.3 Fractional Linear Transformations, Unit Disk

If we have  $\xi = \begin{pmatrix} z_1 \\ z_2 \end{pmatrix}$ , then  $p(\xi) \in \mathbb{D}$  if and only if  $|z_1| < |z_2|$  if and only if  $z_1 \bar{z}_1 - z_2 \bar{z}_2 < 0$ .  
If we let

$$J = \begin{pmatrix} 1, 0 \\ 0, -1 \end{pmatrix},$$

we consider the sesquilinear form  $\langle J \begin{pmatrix} \xi_1 \\ \xi_2 \end{pmatrix}, \begin{pmatrix} \eta_1 \\ \eta_2 \end{pmatrix} \rangle$ , where it is linear in the first coordinate and conjugate linear in the second coordinate. Note that

$$\left\langle J \begin{pmatrix} \xi_1 \\ \xi_2 \end{pmatrix}, \begin{pmatrix} \eta_1 \\ \eta_2 \end{pmatrix} \right\rangle = \xi_1 \bar{\eta}_1 - \xi_2 \bar{\eta}_2.$$

When does  $g \in GL(2, \mathbb{C})$  preserve  $\langle J\xi, \xi \rangle$ ?

This means that

$$\langle Jg\xi, g\xi \rangle = \langle J\xi, \xi \rangle$$

for all  $\xi \in C^2 \setminus \{0\}$ . Then,

$$\langle g^* Jg\xi, \xi \rangle = \langle J\xi, \xi \rangle$$

so it follows that  $g^* Jg = J$ . (We prove this by transforming  $\xi$  in polar coordinates,  $\xi = x + i^k y$ , and considering  $k = 0, 1, 2, 3$ . These four equations allow us to determine the equality). Note that  $U(1, 1) = \{g : g^* Jg = J\}$  forms a group structure where  $J$  has eigenvalues  $\pm 1$  for this reason, we denote  $U(1, 1) \subset GL_2(\mathbb{C})$ .

We claim the following:  $T_g \in \text{Aut}(\mathbb{D}) \Leftrightarrow g \in C^\times \cdot U(1, 1)$ .

## §5 February 3rd, 2021

### §5.1 Remark on the Zeta Function

#### Theorem 5.1 (S.M. Voronin 1975)

For  $D = \{\frac{1}{2} < \operatorname{Re}(z) < 1\}$ ,  $f : D \rightarrow \mathbb{C} \setminus \{0\}$ . If  $K \subset\subset D$  and  $\epsilon > 0$ , then there exists  $t \in \mathbb{R}$  such that

$$\|f(\cdot) - \zeta(\cdot + it)\|_K < \epsilon.$$

This theorem essentially says that if I slide around the zeta function in the strip  $D$ , I can uniformly approximate pretty much any function I want.

### §5.2 Fractional Linear Transformations, continued

Note that  $\operatorname{Ker}(g \mapsto T_g) = \mathbb{C}^\times I_2$ . We define  $SL(2; \mathbb{C}) = \{g \in GL(2; \mathbb{C}) : \det g = 1\}$ , the special linear group.

#### Theorem 5.2

For  $g \in SL(2; \mathbb{C})$ ,  $T_g \in \operatorname{Aut}(\mathbb{D})$  if and only if  $g \in U(1, 1)$ .

*Proof.* We start with the forward direction. From the first homework, we showed that  $f \in \operatorname{Aut}(\mathbb{D})$  implies that  $f(z) = T_g z$  where  $g$  is the composition of a rotation  $g_1$  and  $g_2 = \begin{pmatrix} 1 & z_0 \\ \bar{z}_0 & 1 \end{pmatrix}$  for  $z_0 \in \mathbb{D}$ . It suffices to check that  $g_1, g_2 \in U(1, 1) \times \mathbb{C}^\times I_2$ . This is easy to check.

Now, we show the converse. If  $g \in U(1, 1)$ , then  $g^{-1} \in U(1, 1)$ . If  $z \in \mathbb{D}$ , then  $z = p(\xi)$ ,  $\langle J\xi, \xi \rangle < 0$ . We have  $T_g z = p(g\xi)$  and  $\langle J\xi, \xi \rangle < 0$  implies that  $\langle g^* J g \xi, \xi \rangle < 0$ , which implies that  $\langle J g \xi, g \xi \rangle < 0$ , which shows that  $T_g z = p(g\xi) \in \mathbb{D}$ . Hence  $T_g \mathbb{D} \subset \mathbb{D}$ . The same argument holds for  $T_g^{-1} \mathbb{D} \subset \mathbb{D}$  so we have  $T_g \mathbb{D} = \mathbb{D}$  exactly, so  $T_g = \operatorname{Aut}(\mathbb{D})$ .  $\square$

### §5.3 Automorphisms of the Half Plane

There is a conformal map from  $\mathbb{H}_+ \rightarrow \mathbb{D}$  given by  $f : z \mapsto \frac{z-i}{z+i}$ . This corresponds to

$$f = \begin{pmatrix} 1 & -i \\ 1 & i \end{pmatrix}.$$

Note that

$$f^{-1} = \frac{1}{2} \begin{pmatrix} 1 & 1 \\ i & -i \end{pmatrix}.$$

Now,  $\operatorname{Aut}(\mathbb{H}_+) = \{(T_f)^{-1} T_g T_f | T_g \in \operatorname{Aut}(\mathbb{D})\} = \{T_{f^{-1} g f} | g \in SU(1, 1)\}$ . It follows that  $\operatorname{Aut}(\mathbb{H}_+) = \{T_h | f h f^{-1} \in SU(1, 1)\}$  (assuming  $h \in SL(2, \mathbb{C})$ ,  $f h f^{-1} \in SL(2, \mathbb{C})$ ). It follows that  $(f h f^{-1})^* J (f h f^{-1}) = J$ , so  $h^* (f^* J f) h = f^* J f$ . We can compute

$$f^* J f = \begin{pmatrix} 0 & -2i \\ 2i & 0 \end{pmatrix}.$$

It follows that

$$h^* \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} h = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

If we let  $h = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ , then

$$\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} h^* \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} h = I_2.$$

If we check the computation, we find that  $a, b, c, d \in \mathbb{R}$ , so it follows that  $h \in SL(2, \mathbb{R})$ .

## §5.4 The Cross Ratio

Note that  $T_g$  is completely determined by  $T_g 0, T_g 1, T_g \infty$ . Suppose  $T_g 0 = T_h 0, T_g 1 = T_h 1, T_g \infty = T_h \infty$ . If we let  $r = g^{-1}h$ , we have  $T_r 0 = 0, T_r 1 = 1, T_r \infty = \infty$ , so it follows that  $r \in C^\times I_2$  (carry out the matrix multiplication for an arbitrary matrix).

if we look at  $g^{-1}$  instead of  $g$ , we find that  $T_g$  is completely determined by  $a, b, c \in C \cup \infty$  so that  $Ta = 1, Tb = 0, Tc = \infty$ . Given,  $a, b, c$ , such a  $T_g$  is the map

$$z \mapsto \frac{z - b}{z - c} : \frac{a - b}{a - c}.$$

We denote the RHS by  $(z, a, b, c)$ , which is a fractional linear map taking  $a, b, c$  to  $1, 0, \infty$ . This is called the cross ratio of  $z, a, b, c$ .

### Theorem 5.3

If  $T_g$  is a fractional linear transformation and  $z_1, z_2, z_3, z_4$  are distinct points in  $\mathbb{C} \cup \infty$ , then

$$(z_1, z_2, z_3, z_4) = (T_g z_1, T_g z_2, T_g z_3, T_g z_4).$$

**Remark 5.4.** The above theorem shows that cross ratios are invariant under fractional linear transformations.

## §6 February 8th, 2021

### §6.1 Mappings of Circles and Lines

#### Lemma 6.1

For  $g \in GL_2(\mathbb{C})$ ,  $\{w \in \mathbb{C} \cup \{\infty\} : T_g w \in \mathbb{R} \cup \{\infty\}\}$  is a circle or a straight line with a point at infinity.

*Proof.*

$$\frac{aw + b}{cw + d} = \frac{\overline{aw + b}}{\overline{cw + d}},$$

Then  $(a\bar{c} - c\bar{a})|w|^2 + (a\bar{d} - c\bar{b})w + (b\bar{c} - d\bar{a})\bar{w} + b\bar{d} - d\bar{b} = 0$ . If  $a\bar{c} - c\bar{a} = 0$ , then we have a straight line. If  $a\bar{c} - c\bar{a} \neq 0$ , we have

$$\left| w + \frac{\bar{a}d - \bar{c}b}{\bar{a}c - \bar{c}a} \right| = \left| \frac{ad - bc}{\bar{a}c - \bar{c}a} \right|,$$

a circle. □

### §6.2 Revisiting the Schwarz Lemma

Recall we have  $f \in \text{Aut}(\mathbb{D})$ , with  $f(0) = 0$ . We will use the fractional linear transformations so that  $0 \in \mathbb{D}$  no longer has a special role.

Given  $f : \mathbb{D} \rightarrow \mathbb{D}$  holomorphic with  $z_0 \in \mathbb{D}$ . Take an automorphism mapping  $0 \rightarrow z_0$  given by  $\frac{\cdot + z_0}{1 + \bar{z}_0(\cdot)}$ . Then, applying  $f$  and applying  $(\frac{\cdot + f(z_0)}{1 + \bar{f}(z_0)(\cdot)})^{-1}$ , which sends  $f(z_0) \rightarrow 0$ . These are all holomorphic, so it follows that the composition is a holomorphism from  $\mathbb{D} \rightarrow \mathbb{D}$  mapping  $0 \rightarrow 0$ . Now, we can apply the Schwarz Lemma as usual: For the derivatives, we use the chain rule:

$$\left( \frac{\cdot + z_0}{1 + \bar{z}_0(\cdot)} \right)' \Big|_{z=0} = 1 - |a|^2.$$

Composing the derivatives along the composition, we find the derivative evaluated at 0 which we require to be  $\leq 1$ .

It follows that

$$\frac{|f'(z_0)|}{1 - |f(z_0)|^2} \leq \frac{1}{1 - |z_0|^2}.$$

Moreover, by the Schwarz Lemma, we have equality if and only if  $f \in \text{Aut}(\mathbb{D})$ . if we put  $w = f(z)$ , then  $dw = f'dz$  and the inequality is

$$\frac{|dw|}{1 - |w|^2} \leq \frac{dz}{1 - |z|^2}.$$

This can be interpreted as having on  $\mathbb{D}$  the Riemannian metric

$$\frac{dx^2 + dy^2}{(1 - (x^2 + y^2))^2}$$

and  $f : \mathbb{D} \rightarrow \mathbb{D}$ , contracting the metric.

### §6.3 Functions on Simply Connected Regions

Recall the following properties of holomorphic functions in simply connected regions:

- For  $f : \Omega \rightarrow \mathbb{C}$  holomorphic, then there is  $F : \Omega \rightarrow \mathbb{C}$  holomorphic so that  $F' = f$ .
- $f : \Omega \rightarrow \mathbb{C} \setminus \{0\}$ , then there exists  $g : \Omega \rightarrow \mathbb{C}$  holomorphic so that  $e^g = f$ .
- $f : \Omega \rightarrow \mathbb{C} \setminus \{0\}$  holomorphic, then there exists  $g : \Omega \rightarrow \mathbb{C}$  so that  $h^n = f$ .
- $f : \Omega \rightarrow \mathbb{C}$  holomorphic and non-constant,  $\Omega$  a region, then  $f(V)$  is open if  $V \subset \Omega$ ,  $V$  is open.

### §6.4 Injective Functions

Let  $f : \Omega \rightarrow G$  be a holomorphic function with  $\Omega$  open and connected. If  $f$  is injective, then  $f'(z) \neq 0$ . If so, then  $f(z) - f(z_0) = u(z)^n$  if  $0 = f'(z_0) = \dots, f^{(n-1)}(z_0)$  and  $f^{(n)}(z_0) \neq 0$ , with  $u(z_0) = 0$ . Then  $u(\{|z - z_0| < \epsilon\})$  is open for some  $\epsilon > 0$  so it contains  $\{|\zeta| < \delta\}$  for some  $\delta > 0$ . It follows that  $U(z_k) = \frac{\delta}{z} e^{2\pi i k/n}$  for  $1 \leq k \leq n$  and  $f(z_1) = \dots = f(z_n)$ . We could also use the argument principle to show that  $f'(z) \neq 0$ .

Then,  $f(\Omega)$  is open and  $f$  has local inverses: for each  $z \in \Omega$ , there is a neighborhood  $V_z$ , where  $f$  is a holomorphic isomorphism in the region. It follows that  $f : \Omega \rightarrow G$  is holomorphic, injective, then  $f|f(\Omega) : \Omega \rightarrow f(\Omega)$  is a holomorphic isomorphism.

If  $\Omega$  is an open region so that  $f : \Omega \rightarrow \mathbb{D}$  is a holomorphic isomorphism, then if fix  $z_0 \in \Omega$ , we have  $g \in \text{Iso}(\Omega, \mathbb{D}) \rightarrow (g(z_0), \frac{g'(z_0)}{|g'(z_0)|}) \in \mathbb{D} \times \{|z| = 1\}$  is a bijection.

## §7 February 10th, 2021

### Lemma 7.1

If  $\Omega$  is an open region so that  $f : \Omega \rightarrow \mathbb{D}$  is a holomorphic isomorphism, then if fix  $z_0 \in \Omega$ , we have  $g \in \text{Iso}(\Omega, \mathbb{D}) \rightarrow (g(z_0), \frac{g'(z_0)}{|g'(z_0)|}) \in \mathbb{D} \times \{|z| = 1\}$  is a bijection.

*Proof.* We provide a sketch of the proof. Replace  $f$  with

$$\left( \frac{\cdot - f(z_0)}{1 - \overline{f(z_0)} \cdot} \right) \circ f$$

so that  $f(z_0) = 0$ . Then,  $\text{Iso}(\Omega, \mathbb{D}) \ni g \rightarrow g \circ f^{-1} \in \text{Aut}(\mathbb{D})$  is a bijection and

$$\left( g(z_0), \frac{g'(z_0)}{|g'(z_0)|} \right) = \left( (g \circ f^{-1})(0), \frac{(g \circ f^{-1})'(0)}{|(g \circ f^{-1})'(0)|} \frac{f'(z_0)}{|f'(z_0)|} \right)$$

so the proof reduces to the case where  $\Omega = \mathbb{D}$  and  $z_0 = 0$ . It is easy to show that the map is onto and 1-1.  $\square$

### §7.1 Riemann Mapping Theorem

#### Theorem 7 (Riemann Mapping Theorem)

Suppose  $\Omega$  is simply connected and  $\Omega \neq \mathbb{C}$ . Then, there exists  $f : \Omega \rightarrow \mathbb{D}$  a holomorphic isomorphism.

**Remark 7.2.** There is no holomorphic isomorphism from  $\mathbb{D} \rightarrow \mathbb{C}$  because of Liouville's Theorem.

*Proof.* (Kobe) Let  $z_0 \in \Omega$  and  $\mathcal{F} = \{f : \Omega \rightarrow \mathbb{D} : f \text{ injective}, f(z_0) = 0, f'(z_0) > 0\}$ . The steps are as follows:

- $\mathcal{F} \neq \emptyset$ .

*Proof.* If  $\Omega \neq \mathbb{C}$ , there is a point  $a \in \mathbb{C} \setminus \Omega$ . If  $\Omega$  is simply connected, there exists  $h : \Omega \rightarrow \mathbb{C}$  holomorphic with  $h^2(z) = z - a$ . Then  $h(\Omega)$  is open and there exists  $r$  such that  $B_r(h(z_0)) \subset h(\Omega)$ . Then  $h^2(\cdot) = \cdot - a$  is injective, so  $h$  is injective. Then  $-B(h(z_0), r) \cap h(\Omega) = \emptyset$ . Otherwise, there are  $z_1, z_2$  with  $h(z_1) = -h(z_2) \neq 0$ . Then, we have  $z_1 \neq z_2$  and  $h(z_1) = -h(z_2)$  which implies that  $h^2(z_1) = h^2(z_2)$ .

Hence,  $|h(z) - h(z_0)| \geq r$  for all  $z \in \Omega$ . It we take  $p = r/2 > 0$ , then we have  $|h(z) + h(z_0)| \geq p$ . Then, we find  $c \in \mathbb{C}^\times$  so that

$$c \frac{h(z) - h(z_0)}{h(z) + h(z_0)} \in \mathbb{D}.$$

Rotating by a sufficient  $\theta \in \mathbb{R}$ , we have

$$z \mapsto ce^{i\theta} \frac{h(z) - h(z_0)}{h(z) + h(z_0)} \in \mathcal{F}$$

$\square$

- Show there is  $f$  which maximizes  $f'(z_0)$  in  $\mathcal{F}$ .

*Proof.* Let  $g_n \in \mathcal{F}$  so that  $\lim_{n \rightarrow \infty} g'_n(z_0) = \sup_{f \in \mathcal{F}} f'(z_0)$ . Since  $\|g_n\|_\Omega \leq 1$ ,  $n \in \mathbb{N}$ , we can pass to a subsequence so that  $g_n \rightarrow g$  uniformly on compact subsets of  $\Omega$  for some holomorphic  $g : \Omega \rightarrow \mathbb{C}$  and  $g'_n \rightarrow g'$  uniformly on compact sets in  $\Omega$ . Hence  $\lim_{n \rightarrow \infty} g'_n(z_0) = g'(z_0)$  and  $\sup_{f \in \mathcal{F}} f'(z_0) = g'(z_0) < \infty$  and  $g'(z_0) > 0$ .

We still need to show  $g$  is injective. Let  $z_1 \neq z_2$ ,  $z_1, z_2 \in \Omega$ ,  $g(z_1) = g(z_2)$ . Then in  $\Omega \setminus \{z_1\}$ ,  $g_n(\cdot) - g_n(z_1) \neq 0$  for all points in  $\Omega \setminus \{z_1\}$ . By the Hurwitz theorem,  $g(\cdot) - g(z_1)$  is either 0 or never vanishes. But  $g(\cdot)$  is not a constant function since  $g'(z_0) > 0$ , so we have  $g(\cdot) - g(z_1)$  never vanishes on  $\Omega \setminus \{z_1\}$ , so  $g(z_2) \neq g(z_1)$ , a contradiction.

Moreover,  $\|g\|_\Omega \leq 1$  gives that  $g(\Omega) \subset \overline{\mathbb{D}}$ , but by the maximum principle, we have  $g(\Omega) \subset \mathbb{D}$ .

□

- If  $f'(z_0)$  maximal, then  $f$  is an isomorphism.

*Proof.* It suffices to show that  $g(\Omega) = \mathbb{D}$ . Suppose there is  $w_0 \in \mathbb{D} \setminus g(\Omega)$ . We perform several modifications of  $g$ .

First, let  $F(z) = \sqrt{\frac{g(z) - w_0}{1 - \overline{w_0}g(z)}}$ . This is well-defined since  $\Omega$  is simply connected. Note that  $F(\Omega) \subset \mathbb{D}$  and  $F$  is injective with  $0 \notin F(\Omega)$ .

Second, we make  $z_0$  go to 0. Define  $G(z) = \frac{F(z) - F(z_0)}{1 - \overline{F(z_0)}F(z)}$ . Then,  $G$  is injective from  $\Omega \rightarrow \mathbb{D}$  and  $G(z_0) = 0$ .

We now show that  $G'(z_0) > g'(z_0)$ , a contradiction. We will show that  $g = k \circ G$ , where  $k : \mathbb{D} \rightarrow \mathbb{D}$ , holomorphic. The inverse of  $G$  is a fractional linear transformation given by  $\begin{pmatrix} 1 & F(z_0) \\ \overline{F(z_0)} & 1 \end{pmatrix}$ .

From  $F$  to  $g$ , we take the  $T_w \circ (z \mapsto z^2)$ , where  $w$  is the corresponding matrix from the initial FLT. So we have  $k = T_w \circ (z \mapsto z^2) \circ T_h$ . Note that  $k(\mathbb{D}) \subset \mathbb{D}$  and  $k(0) = \frac{F(z_0)^2 + w_0}{1 + \overline{w_0}F(z_0)^2}$ , so since we have  $F(z_0)^2 = -w_0$ , we get  $k(0) = 0$ .

Since  $k \notin \text{Aut}(\mathbb{D})$ , so we must have  $|k'(0)| < 1$  by the Schwarz Lemma. It follows that

$$|G'(z_0)| > |k'(0)||G'(z_0)| = |(k \circ G)'(z_0)| = |g'(z_0)|,$$

a contradiction.

□

□

## §8 February 17th, 2021

### §8.1 Caratheodory Extension Theorem

**Definition 8.1.** A Jordan curve is given by a map  $[0, 1] \ni t \rightarrow C(t) \in \mathbb{C}$  which is continuous, 1-1 on  $[0, 1]$  and  $C(0) = C(1)$ .

#### Theorem 8 (Jordan Curve Theorem)

If  $C : [0, 1] \rightarrow \mathbb{C}$  is a Jordan curve, then  $\mathbb{C} \setminus C([0, 1])$  has 2 connected components, one of which is bounded and the other is unbounded.

We refer to the bounded component as the interior region, or the Jordan region.

We denote  $C([0, 1])$  as  $|C|$  when  $C : [0, 1] \rightarrow \mathbb{C}$ .

#### Theorem 9 (Caratheodory)

Let  $\Gamma$  be a Jordan curve and  $\Omega$  the bounded region determined by  $\Gamma$  (then  $\partial\Omega = |\Gamma|$ ). if  $f : \mathbb{D} \rightarrow \Omega$  is a holomorphic isomorphism, then  $f$  extends to a homeomorphism  $\overline{\mathbb{D}} \rightarrow \overline{\Omega}$  where  $\partial\mathbb{D}$  is mapped to  $\partial\Omega = |\Gamma|$ .

Some remarks:

- Note that the winding of the boundary around interior points is preserved so correspondence  $\partial\mathbb{D} \rightarrow \partial\Omega$  preserves clockwise orientation (see Ahlfors for more detail).
- It is easy to derive a more general statement for  $\Omega_1, \Omega_2$  of Jordan curves  $\Gamma_1, \Gamma_2$ . So we have homeomorphisms giving  $\Omega_1 \cup |\Gamma_1| = \overline{\Omega_1}$  and  $\Omega_2 \cup |\Gamma_2| = \overline{\Omega_2}$ .
- It also tells us things about regions with slits. For instance, take  $\mathbb{D} \rightarrow \mathbb{D} \setminus [0, 1]$ . By the Riemann Mapping Theorem, we have a holomorphic isomorphism between this set and the unit disk. The boundary behaves as if  $[0, 1]$  would infinitesimally be a double line, but we can still factor a map  $g : \mathbb{D} \cap \{Im(z) > 0\} \rightarrow \mathbb{D} \setminus [0, 1]$ . Then the map  $z \mapsto z^2$  sends this set to  $\mathbb{D} \setminus [0, 1]$ . Then, the homeomorphism  $\partial\mathbb{D} \rightarrow \partial(\mathbb{D} \cap \{Im(z) > 0\})$  is given by Caratheodory.

### §8.2 Rectifiable Arcs

**Definition 8.2.** An arc  $\varphi : [a, b] \rightarrow \mathbb{C}$  is a 1-1, continuous map is rectifiable if it has "length" (bounded variation) that is finite:

$$\sup_{a=t_0 < t_1 < \dots < t_k=b} \sum_{j=0}^{k-1} |\varphi(t_{j+1}) - \varphi(t_j)| < \infty.$$

If this definition is bothersome, we can make stronger assumptions about the arc being piecewise differentiable.

First, we present an analytic continuation theorem. Here the rectifiable arc will be without endpoints  $\varphi : (a, b) \rightarrow \mathbb{C}$ .

**Theorem 10**

If  $\Omega, \omega$  are disjoint regions and  $\Gamma$  a rectifiable arc, so that  $|\Gamma| = \partial\Omega \cap \partial\omega$  and  $|\Gamma| \cap \Omega \cap \omega$  is open. Assume  $f : |\Gamma| \cup \Omega \rightarrow \mathbb{C}$ ,  $g : |\Gamma| \cup \omega \rightarrow \mathbb{C}$  is continuous and  $f|_{\Omega}$ ,  $g|_{\omega}$  holomorphic and  $f|_{|\Gamma|} = g|_{|\Gamma|}$ . Then  $F : \Omega \cup |\Gamma| \cup \omega \rightarrow \mathbb{C}$  defined by  $F|_{\Omega \cup |\Gamma|} = f$ ,  $F|_{|\Gamma| \cup \omega} = g$  is holomorphic.

*Proof.* We sketch the proof. Analyticity is a local property, so we only need to show that for a point on  $|\Gamma|$ , there is a neighborhood where  $F$  is holomorphic. While  $F$  had no endpoints, we take  $\gamma$ , a small portion of the arc. Then, for an open ball containing the arc, we split into regions  $C_1, C_2$ . On this, we define

$$f^*(z) = \frac{1}{2\pi i} \oint_{C_1} \frac{f(\zeta)}{\zeta - z} d\zeta, \quad z \in \Omega_1 \cup \omega_1,$$

going counterclockwise. Similarly, we define  $g^*(z)$  over the lower part. Intersection over  $\gamma$  is a Stieltjes integral.

When we add the two, we get  $F(z) = \frac{1}{2\pi i} \oint \frac{F(\zeta)}{\zeta - z} d\zeta$ . This shows that  $F$  is holomorphic.  $\square$

## §9 February 22nd, 2021

### §9.1 Schwarz Reflection and Variants

Let  $\Omega = \Omega^* = \{\bar{z} | z \in \Omega\}$  an open region. Suppose that  $\Omega \cap \mathbb{R} \subset (a, b)$ . Then,  $\Omega_{\pm} = \omega \cap \{\pm \operatorname{Im}(z) > 0\}$ . If  $f : \Omega_+ \cup (a, b) \rightarrow \mathbb{C}$  continuous and  $f|_{(a,b)} \subset \mathbb{R}$ ,  $f|_{\Omega_+}$  holomorphic, then

$$F(z) = \begin{cases} f(z), & z \in \Omega_+ \cup (a, b) \\ \overline{f(\bar{z})}, & z \in \Omega_- \end{cases}$$

is holomorphic in  $\Omega_+ \cup (a, b) \cup \Omega_-$ .

*Proof.* Use the previous result with  $\Omega = \Omega_+$ ,  $\omega = \Omega_-$ ,  $|\Gamma| = (a, b)$  with  $f = f$ ,  $\overline{f(\bar{\cdot})} = g(\cdot)$ .  $\square$

Variants:

- Suppose we set  $\Omega_+ \subset \mathbb{D}$ ,  $\gamma$ , an arc in  $\{|z| = 1\} \cap \partial\Omega_+$ . We have  $|\gamma| \cup \Omega_+$  open, and  $f : |\gamma| \cup \Omega_+ \rightarrow \mathbb{C}$  continuous,  $f|_{\Omega_+}$  holomorphic and  $f|_{|\gamma|} \subset \mathbb{R}$ .

We set

$$F(z) = \begin{cases} f(z), & z \in \Omega_+ \cup |\gamma| \\ \overline{f(1/\bar{z})}, & z \in \{1/\bar{w} : w \in \Omega_+ \setminus \{0\}\} \end{cases}$$

If we work on the Riemann sphere, we don't need to remove 0, as it gets mapped to  $\infty$ . For circles, we have  $OA \cdot OB = R^2$ .

- Let  $\varphi : (a, b) \rightarrow \mathbb{C}$  be an Analytic arc - that there is  $f : \omega \rightarrow \mathbb{C}$  univalent so that  $\omega \supset (a, b)$ ,  $f|_{(a,b)} = \varphi$ , a holomorphic extension. (this definition avoids the discussion of real analytic functions).

Let  $\Omega$  be a region,  $\gamma$  an analytic arc,  $|\gamma| \supset \partial\Omega$  from univalent  $f : \omega \rightarrow \mathbb{C}$  and we assume  $\omega$  is chosen so that

$$f(\omega \cap \{\operatorname{Im}(z) > 0\}) \subset \Omega, \quad f(\omega \cap \{\operatorname{Im}(z) < 0\}) \cap \Omega = \emptyset.$$

Let  $F : \Omega \cup |\gamma| \rightarrow \mathbb{C}$  continuous.  $F|_{\Omega}$  holomorphic, where  $F(|\gamma|) \subset |\Gamma|$ , where  $\Gamma$  is another analytic arc. Then, there is  $\Omega_1$  open with  $\Omega_1 \supset \Omega \cup |\gamma|$  so that it has  $F$  has a holomorphic extension to  $\Omega_1$  with  $|\gamma|$  mapping to another analytic arc.

First, after a suitable restriction, we take  $g^{-1} \circ F \circ f$ , reducing the result where we have a segment on the real axis mapped to  $\mathbb{R}$ . We then apply Schwarz reflection to the segment.

- Let  $\Omega$  be an inner region of a polygon(not necessarily convex). Suppose  $z_1, \dots, z_n$  appear counterclockwise and  $\alpha_k\pi$ ,  $1 \leq k \leq n$  inner angles  $0 < \alpha_k < 1$  and  $\beta_k\pi$  the outer angles,  $\pi - \alpha_k\pi = \beta_k\pi$  or  $1 - \alpha_k = \beta_k$ . Then  $\sum_k \beta_k = 2$  (the sum of exterior angles is  $2\pi$ ). A function  $f : \Omega \rightarrow \mathbb{D}$  a holomorphic isomorphism has continuous extension to  $\tilde{f} : \bar{\Omega} \rightarrow \bar{\mathbb{D}}$  by Caratheodory with  $\tilde{f}(\partial\Omega) = \partial\mathbb{D}$ . We let  $F : \mathbb{D} \rightarrow \Omega$  be the inverse map. We choose  $f$  so that  $f(z_j) = w_j$ , preserving the counterclockwise orientation.

By the Schwarz Reflection, since  $f((z_k, z_{k+1})) = (w_k, w_{k+1})$ ,  $f$  has an analytic extension across  $(z_k, z_{k+1})$  and some neighborhood of  $(z_k, z_{k+1})$  is mapped injectively into a neighborhood of  $(w_k, w_{k+1})$ . Note that  $F$  has holomorphic extension into a neighborhood of  $(w_k, w_{k+1})$  and etc.

## §9.2 Schwarz-Christoffel Formula

$F : \mathbb{D} \rightarrow \bar{\Omega}$  is a homeomorphism which extends the inverse map and  $F(w_k) = z_k$ .  $\bar{\Omega}$  is a polygon with angles  $\alpha_k\pi, \beta_k = 1 - \alpha_k$ . Then

$$F(w) = C \int_0^w \prod_{i=1}^k (w - w_k)^{-\beta_k} dw + C'.$$

**Remark 9.1.** This is not an explicit formula. The constants  $C, C'$  need to be found and  $w_1, \dots, w_n$  are not known. We can fix  $w_1, w_2, w_3$ , but not more.

*Proof.* Consider a map  $\varphi(\zeta) = \zeta^{\alpha_k} e^{i\omega_k} + z_k$ , which maps a semicircle to the angle  $\alpha_k\pi$ . Note that  $\varphi$  extends to  $\{|\zeta| < \epsilon : \text{Im}(\zeta) \geq 0\}$  and maps  $(-\epsilon, \epsilon)$  to the corner at  $z_k$ . Then  $\tilde{f} \circ \varphi$  maps  $(-\epsilon, \epsilon)$  to an arc of the circle containing  $w_k$ .

Applying the reflection principle to the segment,  $\tilde{f} \circ \varphi$  has an analytic extension to the open disc of radius  $\epsilon$ . Moreover, this extension has nonzero derivative at 0, so it has a local inverse at  $w_k$ .

So, take  $(\tilde{f} \circ \varphi)^{-1}(w) = (w - w_k)K(w)$  with  $K(w_k) \neq 0$  in a neighborhood of  $w_k$ . But then, in a neighborhood of  $w_k$ , if  $w \in \mathbb{D}$ , we have

$$F(w) = \varphi \circ (\tilde{f} \circ \varphi)^{-1}(w) = (w - w_k)^{\alpha_k} \cdot e^{i\omega_k} K(w)^{\alpha_k} + z_k.$$

But  $K(w)^{\alpha_k}$  is holomorphic near  $w_k$  since  $K(w_k) \neq 0$  so we can define (the branch of) this power in a small disc around  $w_k$ . Thus, locally near  $w_k \in \bar{\mathbb{D}}$ , we have

$$F(w) - z_k = (w - w_k)^{\alpha_k} \cdot G_k(w)$$

where  $G_k(w_k) \neq 0$  and holomorphic in a neighborhood of  $w_k$ .

Computing the derivative, we have

$$F'(w) = (w - w_k)^{-\beta_k} (\alpha_k G_k(w) + (w - w_k) G'_k(w))$$

or  $(w - w_k)^{\beta_k} F'(w)$  is holomorphic and nonzero near  $w_k$  so  $F'(w) \prod_{k=1}^n (w - w_k)^{\beta_k}$  is holomorphic near  $\bar{\mathbb{D}}$ .  $\square$
